Pityriasis Rosea in Kaduna, North-West Nigeria: A 20-Year Experience

Pityriasis Rosea à Kaduna, au Nord-Wuest du Nigeria : Une Experience de 20 Ans

H. Yahya

ABSTRACT

BACKGROUND: Pityriasis rosea (PR) is an acute, self-limiting papulosquamous skin disease which predominantly affects children and young adults. Pityriasis rosea appears to be more common in West Africa. Reports about PR from northern Nigeria are few.

OBJECTIVES: To present the relative prevalence, demographic and clinical characteristics of PR.

METHODS: We conducted a retrospective review of records of consecutive patients attending two dermatology clinics in Kaduna, North-West Nigeria between September 2001 and November 2021.

RESULTS: Of 39,037 patients, 922 (2.4%) presented with PR: Median age was 15 years (range 3 months to 63 years) and 24% < 10 years, 60% < 18 years, 87% < 30 years. 62% were female. In patients < 20 years, males were significantly more in number than females (69.6% vs. 60.9%, $P = 0.007$) while in those > 20 years, females were more in number (39.1% vs. 30.4%, $P = 0.007$). The mean duration of disease at presentation was 14 days (range 1 – 240 days). Majority (60%) were seen during the rainy season. A herald patch was present in 67.8%, usually occurring 7 days before the main rash. The trunk was affected by the main rash in 94% while the neck and face were affected in 19.2% and 23.6%, respectively. Itching was reported by 80%. The classic disease constituted 80.2%. Oral involvement was rare.

CONCLUSION: Pityriasis rosea is a common disease in Kaduna. It mostly affects children, adolescents and young adults. Clinical presentation is typical in the majority of patients. Rarely an atypical disease occurs. Oral involvement was rare.

RÉSUMÉ

CONTEXTE: Le pityriasis rosé (PR) est une dermatose papulosquamueuse aiguë spontanément résolutive qui touche principalement les enfants et les jeunes adultes. Le pityriasis rosea semble être plus courant en Afrique de l'Ouest. Les rapports sur la RP du nord du Nigeria sont peu nombreux.

OBJECTIFS: Présenter la prévalence relative, les caractéristiques démographiques et cliniques de la RP.

METHODES: Nous avons effectué un examen rétrospectif des dossiers de patients consécutifs fréquentant deux cliniques de dermatologie à Kaduna, dans le nord-ouest du Nigeria, entre septembre 2001 et novembre 2021.

RESULTATS: Sur 39 037 patients, 922 (2,4 %) ont présenté une RP : l'âge médian était de 15 ans (intervalle de 3 mois à 63 ans) et 24 % < 10 ans, 60 % < 18 ans, 87 % < 30 ans. 62 % étaient des femmes. Chez les patients de < 20 ans, les hommes étaient significativement plus nombreux que les femmes (69,6 % contre 60,9 %, $P = 0,007$) tandis que chez ceux de > 20 ans, les femmes étaient plus nombreuses (39,1 % contre 30,4 %, $P = 0,007$). La durée moyenne de la maladie au moment de la présentation était de 14 jours (fourchette de 1 à 240 jours). La majorité (60%) ont été observées pendant la saison des pluies. Un patch annonciateur était présent chez 67,8%, survenant généralement 7 jours avant l'éruption principale. Le tronc était touché par l'éruption principale dans 94 % tandis que le cou et le visage étaient touchés dans 19,2 % et 23,6 %, respectivement. Des démangeaisons ont été signalées par 80 %. La maladie classique constituait 80,2 %. L'atteinte orale était rare.

CONCLUSION: Le pityriasis rosé est une maladie courante à Kaduna. Elle touche principalement les enfants, les adolescents et les jeunes adultes. La présentation clinique est typique chez la majorité des patients. Rarement une maladie atypique survient. L'atteinte orale était rare. **WAJM 2023; 40(7): 704–709.**
